The Editors
Statistical Methods in Medical Research

Dear Editors,

I am pleased to submit the manuscript “**Statistical Evidence for Halachic Vesset Patterns in Natural Menstrual Cycle Data: A Study of Jewish Religious Law and Menstrual Cycle Regularity — A Permutation and Multinomial Sampling Analysis**” for consideration for publication in *Statistical Methods in Medical Research*.

What this paper does. Jewish religious law (*Halacha*) prescribes that women anticipate menstruation based on recurring patterns in their cycle history, collectively known as *vesset*. Despite their centuries-long practical application, no published study has formally tested whether these patterns occur in real menstrual cycle data at rates exceeding chance. This paper fills that gap using two complementary randomization-based null models — permutation testing and a multinomial sampling null — applied to a publicly available dataset of 1,554 cycles from 118 women (Fehring et al., *Contraception*, 2013).

Methodological contributions. The paper makes three methodological contributions that we believe are of broad interest to readers of this journal:

1. **A joint multivariate test for dependent count vectors.** We introduce a distance-based joint test that evaluates whether a vector of sequentially computed pattern counts is collectively overrepresented relative to a randomization null, without assuming independence among the counts. This test is applicable to any setting where multiple sequential pattern types are counted in time-series or longitudinal data.
2. **A polynomial hierarchy of pattern types.** We show that the five vesset pattern types form a hierarchy based on the order of the finite-difference operator — degree-0 (constant), degree-1 (linear), degree-2 (quadratic) sequences. We derive three mathematically necessary dependence relationships between the patterns (set-theoretic inclusion, limiting convergence, logical incompatibility) and confirm each with pairwise chi-square tests. This motivates the joint test and explains why Bonferroni correction would be logically inappropriate.
3. **A second null model: the multinomial sampling null.** In addition to the standard permutation test, we introduce a multinomial null that draws each woman’s cycle sequence

independently from the fitted empirical distribution, directly encoding the null hypothesis of cycle-to-cycle independence. The close agreement of permutation and multinomial results across all five patterns provides unusually strong evidence of robustness.

Main findings. Haflaga (fixed interval) is significantly overrepresented ($z = 4.51$, $p < .001$), with only 2 of 50,000 permutation simulations reaching the observed count. Dilug (arithmetic progression) is also significant ($p = .043$). A joint multivariate test confirms collective overrepresentation of all five patterns ($p < .01$). A focused joint test restricted to the three mathematically dependent patterns is similarly significant ($p < .01$).

Fit with *Statistical Methods in Medical Research*. This paper sits squarely within the scope of the journal: it develops and applies novel statistical methodology — randomization testing, multivariate distance tests, and null model comparison — to a medical dataset with direct clinical and public-health relevance (menstrual cycle regularity). The interdisciplinary context (Jewish religious law) is unusual, but the statistical methodology and its contributions are entirely general and applicable beyond the halachic setting.

Originality and prior publication. This manuscript has not been submitted elsewhere and is not under review at any other journal. A preliminary analysis appears in the author's PhD dissertation (Ariel University, 2022, in Hebrew), but the present paper extends that work substantially: it introduces the joint multivariate test, the multinomial null model, the polynomial hierarchy with mathematical derivations, the chi-square dependence analysis, and the 5-dimensional geometric visualization, none of which appeared in the dissertation.

Data and code availability. All analysis code and the filtered dataset are publicly available at <https://github.com/dvirross/VesetVectorTest>. The original dataset is archived at Marquette University (https://epublications.marquette.edu/data_nfp/7/).

Suggested reviewers. Given the interdisciplinary nature of this work, I suggest reviewers with expertise in both statistical methodology and reproductive medicine or longitudinal biological data. I am happy to suggest specific names if the editors find this helpful.

I believe this manuscript will be of genuine interest to the readership of *Statistical Methods in Medical Research*, and I look forward to the editorial team's consideration.

Yours sincerely,

Dvir Ross, PhD

Declarations

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Conflict of interest

The author declares no conflicts of interest.

Ethics approval

This study is a secondary analysis of a publicly available, fully anonymised dataset (Fehring et al., 2013, archived at Marquette University). No new data collection was conducted. No ethical approval was required.

Patient consent

Not applicable. No new data were collected. The original dataset was collected under the ethical oversight of the original investigators (Fehring et al., 2013).

Data availability

The filtered dataset and all analysis code used in this study are publicly available at <https://github.com/dvirross/VesetVectorTest>. The original NFP dataset is archived at Marquette University: https://epublications.marquette.edu/data_nfp/7/.

Author contributions
